Use of a high-resolution ultrasound probe and 3D ultrasound imaging to measure the length of the long head of the biceps brachii tendon in the glenohumeral joint. The length of the long head of the biceps brachii tendon (LHB) in the glenohumeral joint (GHJ) is assumed to have a strong relationship with subacromial impingement and rotator cuff (RC) tendonitis. There is no agreement on the proper way to measure this length. Most methods have relied on using a clinical ruler or calipers. We aimed to quantify LHB length using an ultrasound imaging and mapping system (Philips iU22). The LHB length was measured in 68 subjects (mean age = 35.7 years, SD = 7.1; 57% male), with a range of motion of 29° to 175°. We used a high-resolution, linear, and transducer in the anterior-posterior and superior-

inferior planes at the GHJ. Multiple linear regression analysis was performed on the LHB length and also on the glenoid version and the RC thickness. We performed a Pearson's r correlation analysis of the LHB length and external rotation and internal rotation strength. Our results demonstrate that in the supine position, LHB length can be measured using a high-resolution ultrasound imaging and mapping system in the anterior-posterior and superior-inferior planes at the GHJ. LHB length varied between 30 and 65 mm. There was a significant negative correlation between LHB length and external rotation ($r = -0.3$) and internal rotation ($r = -0.3$). No significant correlation was found between LHB length and the glenoid version or RC thickness. LHB length can be reliably measured using the anterior-posterior and superior-inferior plane of the GHJ with a high-resolution ultrasound imaging and mapping system. The effect of the stage of gestation on the pH of maternal and fetal bile. The effects of the stage of gestation on the pH of maternal and fetal bile have 2d92ce491b
