Among conventional electronic article surveillance (hereinafter referred to as "EAS") systems there is one in which a card-like or card-like circuit board having a magnetically conductive element mounted thereon is inserted into the interior of an article to be protected. The card-like or card-like circuit board has a magnetically conductive member mounted on a magnetic field transmitting member of a thin plate-like thermally responsive element. This element consists of a thermally responsive body having a permanent magnet (M) on its one surface and a magnetic field transmitting member made of a magnetic material having a magnetic force more than that of the permanent magnet on the other surface. In the above-mentioned EAS system, the magnetically conductive member is contacted with a detection circuit (magnetically conductive and insulated member) by a magnetic force, and thereby the presence or absence of the card-like circuit board inserted into the article is detected. However, the conventional thermo-responsive element mentioned above is defective in that when the magnetic force of the permanent magnet is greater than that of the magnetic field transmitting member, the hysteresis characteristic of the thermally responsive body becomes large, and as a result the difference in the applied magnetic force between the heating and the cooling thereof becomes very large, thereby causing an error in the temperature detection. In order to eliminate such an error, it has been proposed to use a material having a magnetic force more than that of the magnetic field transmitting member as the magnetic field transmitting member. However, it has been found that the conventional material used for this purpose has its magnetic force fixed or becomes more magnetic with the lapse of time. This means that it becomes necessary to consider the difference in magnetic force due to the lapse of time in accordance with 2d92ce491b
