Vesicovaginal fistulas are infrequent. Although surgical repair is the preferred treatment option for these fistulas, results in the literature are variable and patient outcomes can be prolonged and unpredictable. A retrospective chart review was performed of patients treated for vesicovaginal fistula between January 2000 and December 2007. Age, fistula etiology, type of repair, time to repair, and other variables were recorded. Primary fistula closure was defined as fistula closure within 3 months of surgery, whereas secondary fistula closure was defined as fistula closure >3 months after surgery. Twenty-nine patients with a vesicovaginal fistula were identified, of which 22 (75%) were repaired with fistula repair alone, whereas 7 (25%) were repaired with fistula repair plus adjunctive procedures (myocutaneous flaps or omental flaps). The most common etiology was obstetric trauma (35.7%). Most of the fistulas were simple (71.4%). The primary repair rate was 75%, with a secondary repair rate of 25%. Fistula repair alone resulted in primary closure in 18 of 22 patients (81%). Fistula repair plus myocutaneous flap resulted in primary closure in 3 of 7 patients (43%). Repair of vesicovaginal fistulas is associated with a high success rate when performed with a fistula repair alone. In the setting of complex fistulas, fistula repair with additional myocutaneous flap or omental flap coverage increases the likelihood of fistula closure. Statins and cancer risk: mechanistic insights and recommendations. For many years, the potential role of cholesterol and lipids in the development of cancer has been controversial. High cholesterol levels and the lipid-lowering drugs that lower them have been associated with a reduced risk of several cancers, including breast, colon, prostate, and lung cancer. However, a relationship with cardiovascular disease mortality is suggested for the benefit seen with statins in the primary and secondary prevention of cardiovascular disease, and for the post-treatment risk of myopathy. Although the data for the benefit of statins in cancer prevention are strong, there is no evidence that statins increase the risk of cancer. The available data on the association between stat
